Highlights

- Imaging quality (NESZ, resolution) added as multi-objective scheduling targets
- Edge contracts with density and agility; negligible beyond N = 150 (simulated)
- Re-optimisation +40% radiometric (15% cost); squint-min greedy +45% (49%)
- Third objective +4.9% (matched rule) vs +0.05% radiometric-blind null
- Ablation over 1200 runs: physics objectives matter only when squint is wide
